

This node is the core node to connect with the BE Logic Objects. It has 3 concerns:
On Begin / Logic Object / On End :
When it is reached, "One Begin" section is where user define how to create payload to send to the Logic Object . After that, Run the Logic Object. After receiving the response from Logic Object, it format the data as instructed by the "On End" section. Only then, It token is read to passed to next block

Process

When a Split Block is reached, all blocks after it will get assigned a token

Split

When a Join Block is Reached, All blocks before it must keep a token so it can progress

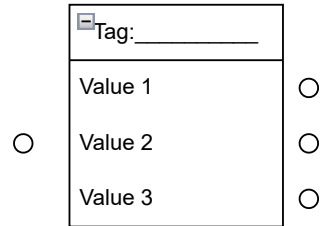

Join

When a Merge Block is Reached, Any time any one or more of the blocks before it has a token -> it progress

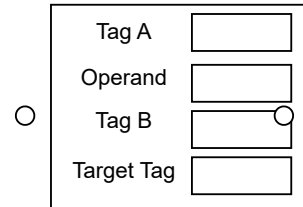

Merge

When a Switch block is reached, it take a value from a Tag and examine it value. Thne decide which way it will pass the token to

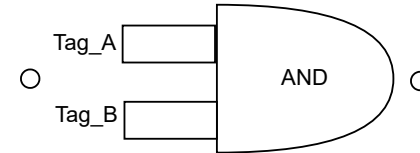

Switch

When a compute block is reached. It takes a value from a tag, does an operand on another tag, then finally writes the result into a target tag

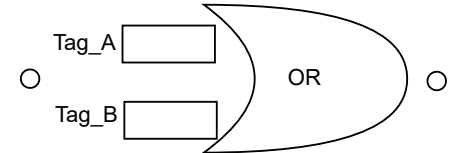

Compute

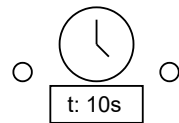

Examine value from 2 boolean Tags and decide if the token can be passed or not by AND operator

Examine value from 2 boolean Tags and decide if the token can be passed or not by OR operator

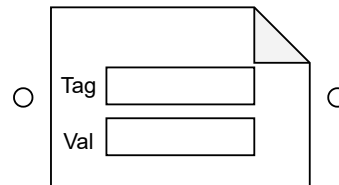

If a token is passed into Delay block. It must wait the x amount of time before getting passed to next block

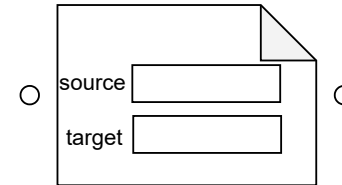

Delay

When Tag overwrite (by val) block is reached. A selected Tag will have it value overwritten with some input value

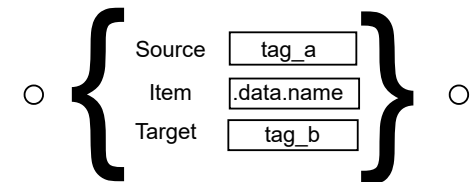

Tag overwrite
(by val)

When Tag overwrite (by tag) block is reached. A selected tag will have its value overwritten with another tag's value

Tag overwrite
(by tag)

This Extract JSON block will get a value from a tag (which contains a JSON). then treate it as if it is a json, try to get an item out of it then write to a target tag. If the data cannot be extract -> write to error tag

Extract JSON
